This report provides a general plotting routine to express 2 dimensional tabular data in logarithmic or linear graphical form. The program contains a scaling routine to maximize plot coverage and calculate axis length and tick marks. The routines are written in Fortran IV computer language and designed to run on a Hewlett-Packard HP 1000 computer system with Graphics 1000 plotting software and a graphics terminal or plotter.

#### A FORTRAN IV PROGRAM TO SCALE AND PLOT LOGARITHMIC AND LINEAR DATA

#### Introduction

The need to represent data in a form more meaningful than tabular has prompted the development of new software for general scientific use. Our specific needs in chemical experimentation require the capability for plotting of a wide variety of X vs. Y data types, with and without "error bar"—type error limits on each data point. In addition, it is often necessary to do least squares calculations on these same data and plot a least squares regression line on the same plot for visual indication of linearity, scatter and goodness-of-fit. Finally, the capability to provide journal-ready plots to eliminate the need for the user to make decisions about scaling is highly desirable.

Program LPLOT satisfies these basic requirements and contains such additional capabilities as log, semi-log or linear axes, multiple data sets on a single graph, multi-colored plots and variable origin starting location. The main routine does the plotting; five subroutines handle the log and linear scaling, log and linear axis drawing and calculation of a least squares regression. All six routines are written in Fortran IV. (1) This software was developed to provide maximum flexibility with a minimum of effort by the user. It is designed to run on a Hewlett-Packard 1000 computer system under an RTE IV operating system and makes use of the device-independent features of Hewlett-Packard's Graphics-1000 Software as well as some H.P. extensions to standard Fortran IV.

The most desirable feature of program LPLOT is that the calls to external routines are only to control plotter pen motion, this makes the program easily adaptable to run with any graphic package.

This document is designed to serve the purposes of a users' guide and an operations manual, and to provide sufficient documentation for program maintenance.

Manuscript submitted January 19, 1981.

## Features of Program

- 1. Automatic linear and logarithmic scaling.
- 2. Choice of linear, semi-log, or logarithmic axes.
- 3. Least squares line with slope, Y-intercept and standard deviations of each.
- 4. Error bars.
- 5. Multiple plots with different symbols on same graph.
- 6. Data source can be from disc file, cartridge or paper tape or typed in from the keyboard of a terminal.
- 7. Output can be on graphics terminal or plotter.
- 8. Plots can be line, symbols, or symbols connected by line.
- 9. Axis labeling and title are entered from terminal.
- 10. Origin can be determined automatically or forced to start at (0,0).
- 11. Tick marks are labeled.
- 12. Multiple color plots with automatic pen changing.
- 13. A manual scaling option can plot multiple data sets, which have different maximum and minimum values, on a single set of axes.
- 14. The routine can handle up to 256 points per data set.

## Computer and System Configuration

This program could be modified to run on many different computers with different plot packages; however, this routine was written for the Hewlett-Packard HP 1000 family of computers using Graphics-1000 (HP 92840A graphics plotting software). The operating system is RTE IVB with updated software revision code 2001. A graphics device, HP 2648A graphics terminal and/or HP 9872B plotter, is needed to do the plotting. Older versions of the RTE operating system and earlier plotters can be used so long as graphics 1000 limitations are satisfied. EMA and spooling features were not utilized. This routine requires a 26K-word partition to run.

#### User Changes

This program was tested on a system probably configured differently from that of the user. It is the responsibility of the user to make changes to logical unit assignments to implement this program on his system. Changes will need to be made to lines 39 through 44, 49, 299 and 390 of program LPLOT. LUG is the logical unit number of the graphics device. ID is the identification number assigned by the device link table to a graphics logical device. Line 68 of program LPLOT does not permit a logical unit number greater than 30. This limit was set to avoid input errors and may need to be changed by the user.

#### Program Background

The Hewlett-Packard Graphics 1000 plot package (HP 92840A) does not provide logarithmic plotting, linear or logarithmic scaling. It is left for the user to determine the limits of the data and how the axes of a plot are to be annotated.

The existing graphics software forces the user to draw two linear axes with one call to an axes drawing routine. This action restricts both axes anotation to one format. Program LPLOT is not limited by this restriction because it uses two calls, one for each axis, so each axis can be anotated differently.

The need to represent data logarithmically as opposed to linearly is evident when data spans many orders of magnitude or conforms to logarithmic interpretation.

It is because of these needs and restrictions program LPLOT was written.

#### Cautions

Erroneous control codes in a data file or failure to separate data with a comma or space can produce unpredictable plotting results.

Data files set up for error bar plotting must set DELX and DELY equal to zero for those data points where error bars are not desired.

The subroutine SCALE transforms the array A into exponential notation, storing the exponent in IEXP. This process changes the array A by some factor of 10. If the user calls this subroutine from any other program he should be aware that any value passed back to the calling routine could be changed. It is for this reason A and IEXP must be used together.

A symbol type plot cannot center a symbol directly on an axis because the plotting window boundary is set on the axis and calls cannot be made to plot outside this area.

Some errors in input data can generate error conditions in Hewlett-Packard library routines. As written, the program allows these to be printed on the standard list device (logical unit 6). To avoid this, the user must supply his own error routine as described in relocatable library routine ERO.E. (2)

The user should be aware that significance in single precision real format is to six or seven decimal digits. It is due to this limitation that plotting errors will be encountered if input data exceedes this limit.

#### Input

Data can be input to the program from a disc file, cartridge or paper tape or typed in from the keyboard of a terminal. Disc files must be type 3 or 4. (3) The program can handle an array up to 256 data points. The format is X, Y, DELY, DELY using free field input. (4) The X and Y pair is the position of the point along the X and Y axis respectively. The optional pair DELX and DELY is the standard deviation in X and Y. These values are used for drawing error bars and will be doubled and scaled to plotter units to provide the horizontal or vertical separation of error bars. All numeric input data must be in the range of 10<sup>-38</sup> to 10<sup>38</sup>.

## Loading Procedure on HP 1000

The loader must be loaded as a large background program (type 4) and will require a size of 26 pages to accommodate the Graphics-1000 routines. After compiling &LPLOT, &SCALE, &LSCAL, &LINAX, &LOGAX and &LSREG, execute the loader on the command file or interactively as follows:

RU, LOADR	RE, %LINAX
SZ,26	RE, %LOGAX
OP,LB	RE, %LSREG
RE, LPLOT	RE, *DLTBL
RE, &SCALE	SE, %GPS
RE, %LSCAL	END

where %DLTBL is the device link table and %GPS is the Graphics-1000 library file created when Graphics-1000 was loaded. (5) Alternatively, the source version available from the author contains a loader command file which can be used. The loaded program will occupy approximately 26K words of memory. It would be possible to decrease the main program space somewhat by using EMA (6) for array space. However, the bulk of this 26K words is required for Graphics-1000 routines.

#### Program Source Availability

A program source is available from the author on a user-supplied Hewlett-Packard 264X-type cartridge tape. This tape contains 8 files. The first file is a description of what is on the tape. The second file is a command file which may be used by the loader to load the programs. The third file is the source for program LPLOT. The fourth file is the source for subroutine SCALE. The fifth file is the source for subroutine LSCAL. The sixth file is the source for subroutine LINAX. The seventh file is the source for subroutine LOGAX. The eight file is the source for subroutine LSREG.

#### Error Messages

Program LPLOT checks for errors that could occur when reading a disc resident file. Messages to the user are sent with the name of the file if a problem is encountered. The program has several built in checks to catch typing errors by the user.

#### Testing of Program

The author has used a wide variety of data types, multiple files, and several input sources to debug this program. In addition, the program has been used extensively by other individuals with different applications.

#### Execution of Program

The execution of LPLOT can be performed by supplying terminal and graphics device Logical Unit Numbers (LU and LUG) via the run string parameters. These parameters (globals) are retrieved by a call to the Hewlett-Packard routine RMPAR in LPLOT. If these parameters are not supplied, the program retrieves LU and prompts the user for the graphics device LUG. Device selection is to be made between the plotter, for a hard copy, or the graphics terminal. The data source is from a disc file, cartridge or paper

tape or entered via the keyboard of a terminal. If the source is a disc file the name of the file is requested. If the source is other than the disc a logical unit number is requested. One of three types of plots can be selected; a straight line connecting each point, a symbol at each point or a symbol at each point with connecting lines. The user may select either axis to be linear or logarithmic. Labels are entered from the users terminal, any ASCII character is permitted (capital and lower case letters, numbers and symbols). The X and Y axis labels cannot exceed 30 characters and the title of the plot cannot exceed 40 characters in length; characters beyond these limits are ignored. The starting position of the origin can be forced to start at X = 0 and Y = 0 or the user can let the scale routine determine an origin that will maximize the size of the plot vs. the size of the axes. Scaling is performed automatically, however a manual override is provided. The manual scaling mode is used to increase the limits between the maximum and minimum values of an axis. This feature is necessary when plotting multiple plots on one graph when the maximum and minimum values of all of the data sets are not within one data set. When plotting multiple data sets the first set plotted must have the smallest and largest values of all of the data sets. If this condition cannot be met the user must specify manual scaling and enter minimum and maximum values of the entire set of data. A least squares line can be drawn on the plot with slope, y-intercept and respective standard deviations printed on the users terminal or printer. Error bars can be drawn around each point provided requirements in the input section of this paper have been met. Error bars that are small enough to distort the symbol printed at a data point are suppressed and a message is printed on the users terminal of this action. Six or less plots can be made using the same set of axes provided all data sets fall within the limits of the first data set plotted. The user has the option to make pen color changes when doing multiple plots on the same axes.

#### Subroutines

The axis drawing and scaling subroutines of program LPLOT do not make calls to external routines other than for plotter pen movements.

The subroutine SCALE uses a table look-up method, based on the difference between maxinum and minimum values, to determine axis scaling and number of tick marks to be placed on each axis. The SCALE routine uses an algorithm that shifts decimal points to increase numbers that are less than one and decrease numbers that are greater than 1000.

The subroutine LSCAL logarithmically scales an array to determine the exponent to which the base 10 must be raised to produce a number less than or equal to the minimum value of the array and greater than or equal the maximum value of the array.

The subroutine LINAX draws a linear axis and labels tick marks in the X or Y direction.

The subroutine LOGAX draws a lograthmic axis and labels tick marks in the X or Y direction.

The subroutine LSREG does a least squares regression calculation including the standard deviation of the slope and y intercept.

#### Plotter Set Up

The HP 9872B plotter is used when hardcopy results of LPLOT are required. The plot generated by LPLOT is designed to fit on standard 8½ X 11 inch paper with adequate margins for publication. In order to center the plot the paper must be placed horizontally ½ inch from the left side and 1 inch from the bottom of the plotter bed. This displacement is necessary because the HP 9872B plotter with advance option OFF places the lower left corner of the plotting window at (520, 380) instead of (0,0). For multicolored plots pen placement is as follows; pen 1 is black, 2 is red, 3 is green, and 4 is blue. If the plot is to be one color that color pen must be in pen holder 1.

## Plotting Accuracy

The HP 9872B plotter is divided into plotter units where one unit = 0.025 mm. This is to say that the overall resolution of the plot is one part in N where N is the number of plotter units occupied in the X or Y direction. The X axis is 7.7 inches (7,823 plotter units) and the Y axis is 5.25 inches (5,334 plotter units). The plotter resolution is one part in 7,823 in the X direction and one part in 5,334 in the Y direction.

#### Mnemonic List

BARX - Minimum value of X error bar

BARY - Minimum value of Y error bar

DELX - Experimental error in X (standard deviation)

DELY - Experimental error in Y (standard deviation)

DIF - Difference between maximum and minimum

HH - Half height in character cells

HW - Half width in character cells

IAX - Label of X axis (30 characters max)

IAXES - Type of plot (log and/or linear)

IAY - Label of Y axis (30 characters max)

IBAR - Type of error bars

ID - Identification number

IDONE - Check for termination or multiple plot

IEXP - Exponent of base 10 in X data scale

IFMT - Source of data

IHED - Title of plot (40 characters max)

ILINE - Check for least squares line

IPEN - Pen number of plotter

ISCAL - Set to zero for automatic scaling, 1 for manual

IZERO - Set to zero to force origin to start at zero

JCHAR - Character to be plotted at each data point

JEXP - Exponent of base 10 in Y data scale

JJ - Type of plot

KK - Number of plots on same axes

LU - Logical unit

LUG - Logical unit of graphics device

LUT - Logical unit of cartridge tape or keyboard

NAME - Name of data file

NOBAR - Check to see if error bar was too small to plot

NP - Number of points

S1 - Standard deviation of slope

S2 - Standard deviation of Y intercept

SLOPE - Slope of least squares line

SXTIC - Interval between X tick marks

SYTIC - Interval between Y tick marks

X - Displacement along X axis

XBAR1 - Distance to left of character of X error bar

XBAR2 - Distance to right of character of X error bar

XEND - X value at end of least squares line

XMAX - Maximum value of X

XMIN - Minimum value of X

XST - X value at start of least squares line

XTIC - Number of tick marks on X axis

Y - Displacement along Y axis

YBAR1 - Distance above character of Y error bar

YBAR2 - Distance below character of Y error bar

YEND - Y value at end of least squares line

YINT - Y intercept of least squares line

YMAX - Maximum value of Y

YMIN - Minimum value of Y

YST - Y value at start of least squares line

YTIC - Number of tick marks on Y axis

## Formulas

The following formulas were used in subroutine LSREG:

Slope = 
$$\frac{(DIF)(\Sigma X \Sigma Y) - (\Sigma X \Sigma Y)}{(DIF)(\Sigma X)^2 - (\Sigma X)^2}$$

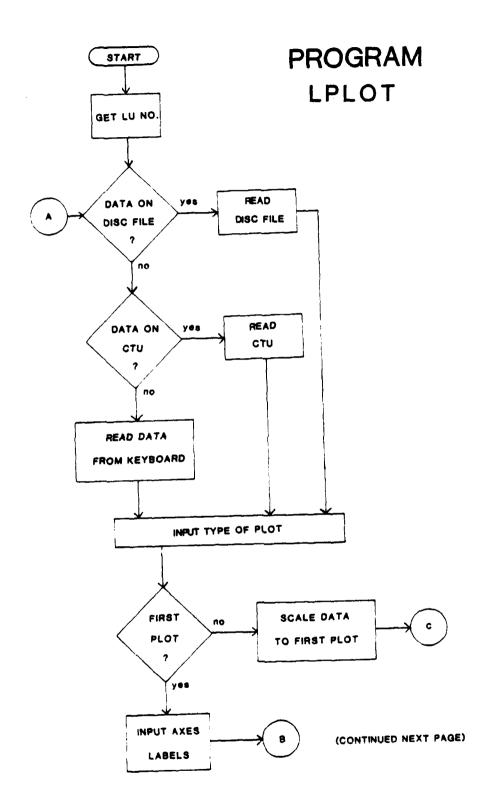

Y-Intercept = 
$$\frac{\Sigma Y - (SLOPE)(\Sigma X)}{DIF}$$

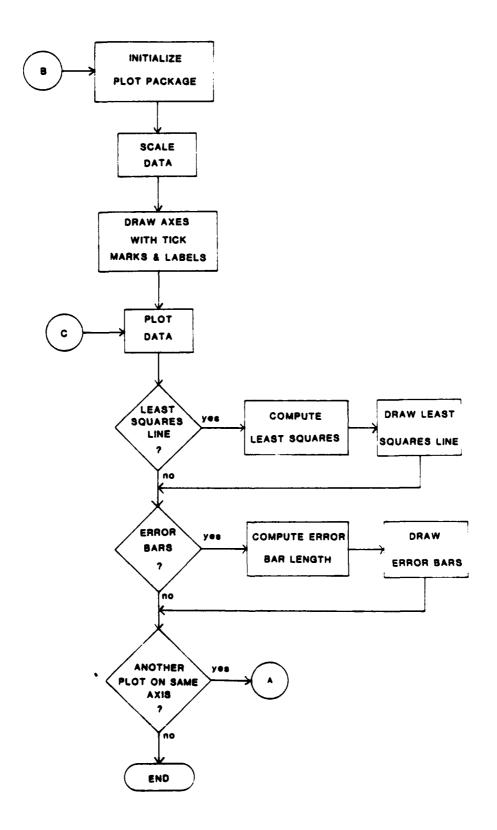

$$Y^{2} - \frac{(\Sigma Y)^{2}}{DIF} - \frac{(\Sigma X\Sigma Y) - \frac{\Sigma X\Sigma Y}{DIF}}{\Sigma X^{2} - \frac{(\Sigma X)^{2}}{DIF}}$$
Standard Deviation of Slope = 
$$\sqrt{(SD \text{ of } SLOPE)^{2} \cdot \frac{\Sigma X^{2}}{DIF}}$$
Standard Deviation of Y Intercept = 
$$\sqrt{(SD \text{ of } SLOPE)^{2} \cdot \frac{\Sigma X^{2}}{DIF}}$$

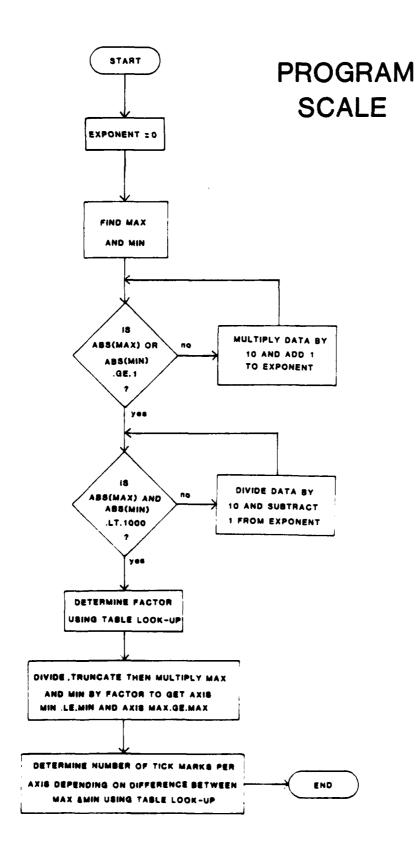

DIF = the interval over which the calculation is computed (FROM-TO+1)

 $\Sigma X$  = summation of X values

 $\Sigma Y = summation of Y values$
